A complex, abstract 3D rendering of a human head and shoulders. The model is composed entirely of thin, dark grey lines forming a dense, organic mesh. The facial features, including the eyes, nose, and mouth, are defined by these lines, giving it a skeletal and fluid appearance. The lighting is dramatic, highlighting the contours and depth of the sculpture against a plain white background.

Advanced Creative Coding with Three.js

Dr. Stavros Didakis (Session 1)

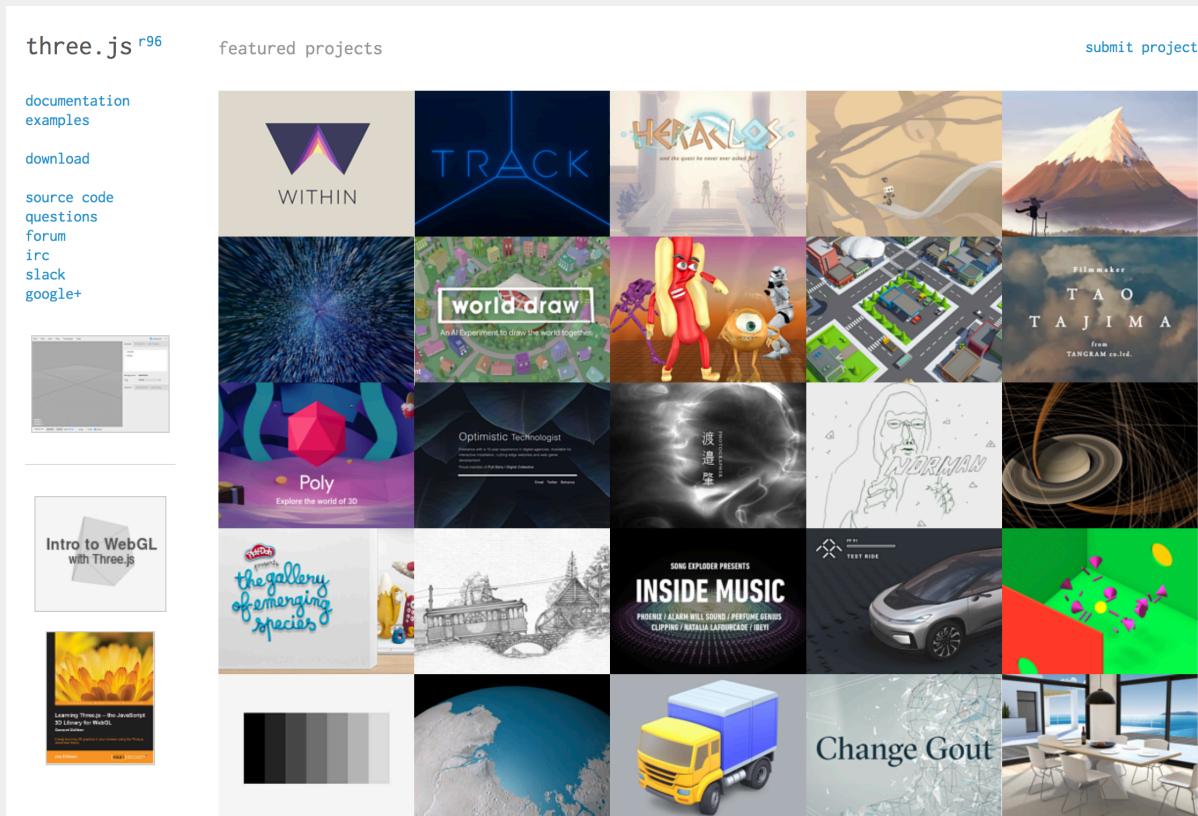

THREEJS INTRO

Three.js (threejs.org)

Three.js is a cross-browser JavaScript library and Application Programming Interface (API) used to create and display animated 3D computer graphics in a web browser.

Three.js allows the creation of Graphical Processing Unit (GPU)-accelerated 3D animations using the JavaScript language as part of a website without relying on proprietary browser plugins.

Three.js utilizes the power of WebGL (and related libraries, such as WebAudio, WebVR, etc).

WebGL

WebGL (Web Graphics Library) is a JavaScript API for rendering interactive 2D and 3D graphics within any compatible web browser without the use of plug-ins. WebGL is integrated completely into all the web standards of the browser, allowing GPU-accelerated usage of physics and image processing and effects as part of the web page canvas.

WebGL elements can be mixed with other HTML elements and composited with other parts of the page or page background.[3] WebGL programs consist of control code written in JavaScript and shader code that is written in OpenGL ES Shading Language (GLSL ES), a language similar to C or C++, and is executed on a computer's graphics processing unit (GPU).

WebGL & Three.js

With WebGL, you can directly make use of the processing resources of your graphics card and create high-performance 2D and 3D computer graphics. Programming WebGL directly from JavaScript to create and animate 3D scenes is a very complex and error-prone process. Three.js is a library that makes this a lot easier.

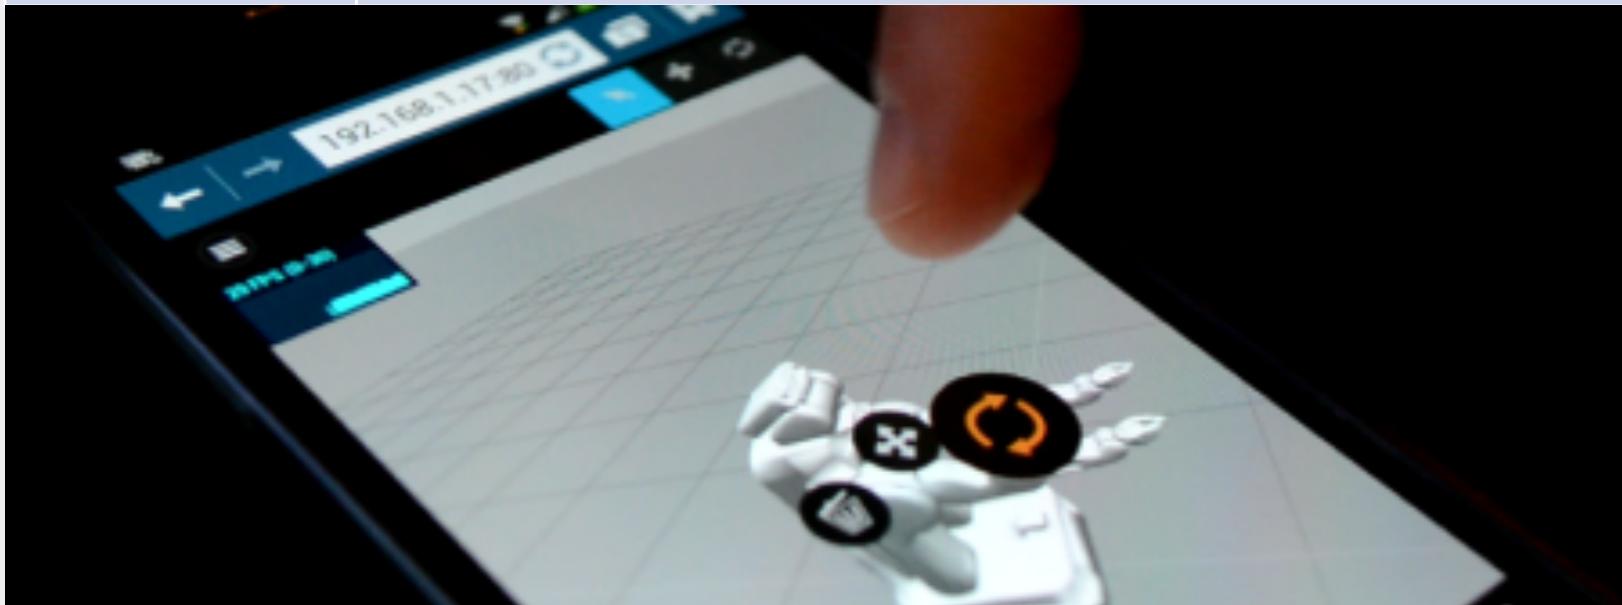

Basically, Three.js runs on any of the modern browsers except older versions of IE.

Browser	Support
Mozilla Firefox	This browser has supported WebGL since version 4.0.
Google Chrome	This browser has supported WebGL since version 9.
Safari	Safari Version 5.1 and newer installed on Mac OS X Mountain Lion, Lion, or Snow Leopard supports WebGL. Make sure you enable WebGL in Safari. You can do this by going to Preferences Advanced and checking Show develop menu in menu bar . After that, go to Develop Enable WebGL .
Opera	This browser has supported WebGL since version 12.00. You still have to enable this by opening opera:config and setting the values of WebGL and Enable Hardware Acceleration to 1. After that, restart the browser.
Internet Explorer	Internet Explorer was for a long time the only major player that didn't support WebGL. Starting with IE11, Microsoft has added WebGL support.

WebGL & Three.js

It is also possible to run Three.js on mobile devices.

Device	Support
Android	The native browser for Android doesn't have WebGL support and is generally also lacking in support for modern HTML5 features. If you want to use WebGL on Android, you can use the latest Chrome, Firefox, or Opera mobile versions.
iOS	With iOS 8, there is also support for WebGL on iOS devices. iOS Safari version 8 has great WebGL support.
Windows mobile	Windows mobile supports WebGL since version 8.1.

Development Tools

To start developing a project for **Three.js**, it is necessary to have a code editor for managing the project. There are mainly two archetypes: IDE (Integrated Development Environment), and lightweight editors such as:

- Sublime
- Atom
- Brackets

In this workshop we will be using **Atom**, as it seems the most efficient editor with the best **Git** and **GitHub** integration, and **Chrome** as the preferable web browser.

Atom (<https://atom.io>)

Atom is a cross-platform text editor with a large number of features such as a built-in package manager and highly effective customization.

Full-featured, right out of the box

Cross-platform editing

Atom works across operating systems. You can use it on OS X, Windows, or Linux.

Built-in package manager

Search for and install new packages or start creating your own—all from within Atom.

Smart autocomplete

Atom helps you write code faster with a smart, flexible autocomplete.

File system browser

Easily browse and open a single file, a whole project, or multiple projects in one window.

Multiple panes

Split your Atom interface into multiple panes to compare and edit code across files.

Find and replace

Find, preview, and replace text as you type in a file or across all your projects.

Welcome

Welcome Guide

ATOM

A hackable text editor for the 21st Century

For help, please visit

- The Atom docs for Guides and the API reference.
- The Atom forum at [discuss.atom.io](#)
- The Atom org. This is where all GitHub-created Atom packages can be found.

Show Welcome Guide when opening Atom

Git and GitHub

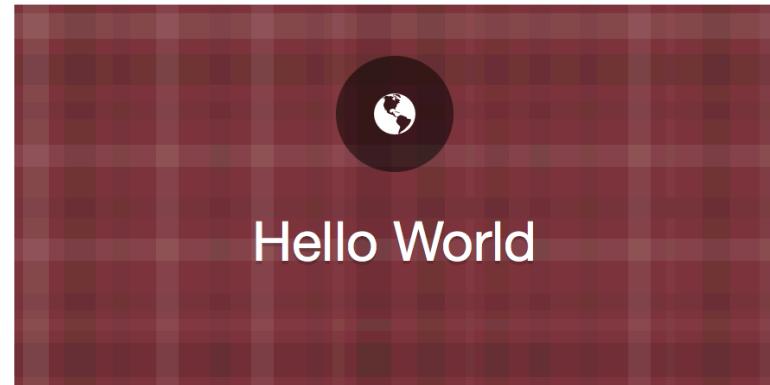

GitHub Flow is a lightweight, branch-based workflow that supports teams and projects where deployments are made regularly. This guide explains how and why GitHub Flow works.

⌚ 5 minute read

GitHub Pages are a great way to showcase some open source projects, host a blog, or even share your résumé. This guide will help get you started on creating your next website.

⌚ 10 minute read

The easiest way to get started with GitHub. In this guide you'll complete a time honored "Hello World" exercise, and learn GitHub essentials.

⌚ 10 minute read

Learn about version control—in particular, Git, and how it works with GitHub.

⌚ 10 minute read

Atom & GitHub

Here is a short video introduction of Atom:

<https://www.youtube.com/watch?v=U5POoGSrtG>

A link to the official documentation:

<https://atom.io/docs>

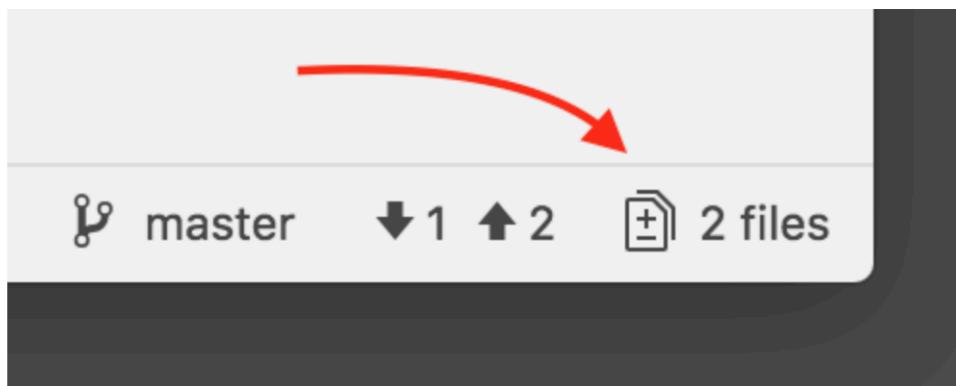

And more info on setting up Git and Github:

<http://flight-manual.atom.io/using-atom/sections/github-package/>

Most of the functionality lives in the Git and GitHub panel. There are different ways to access them, probably the most common way is through their keybindings:

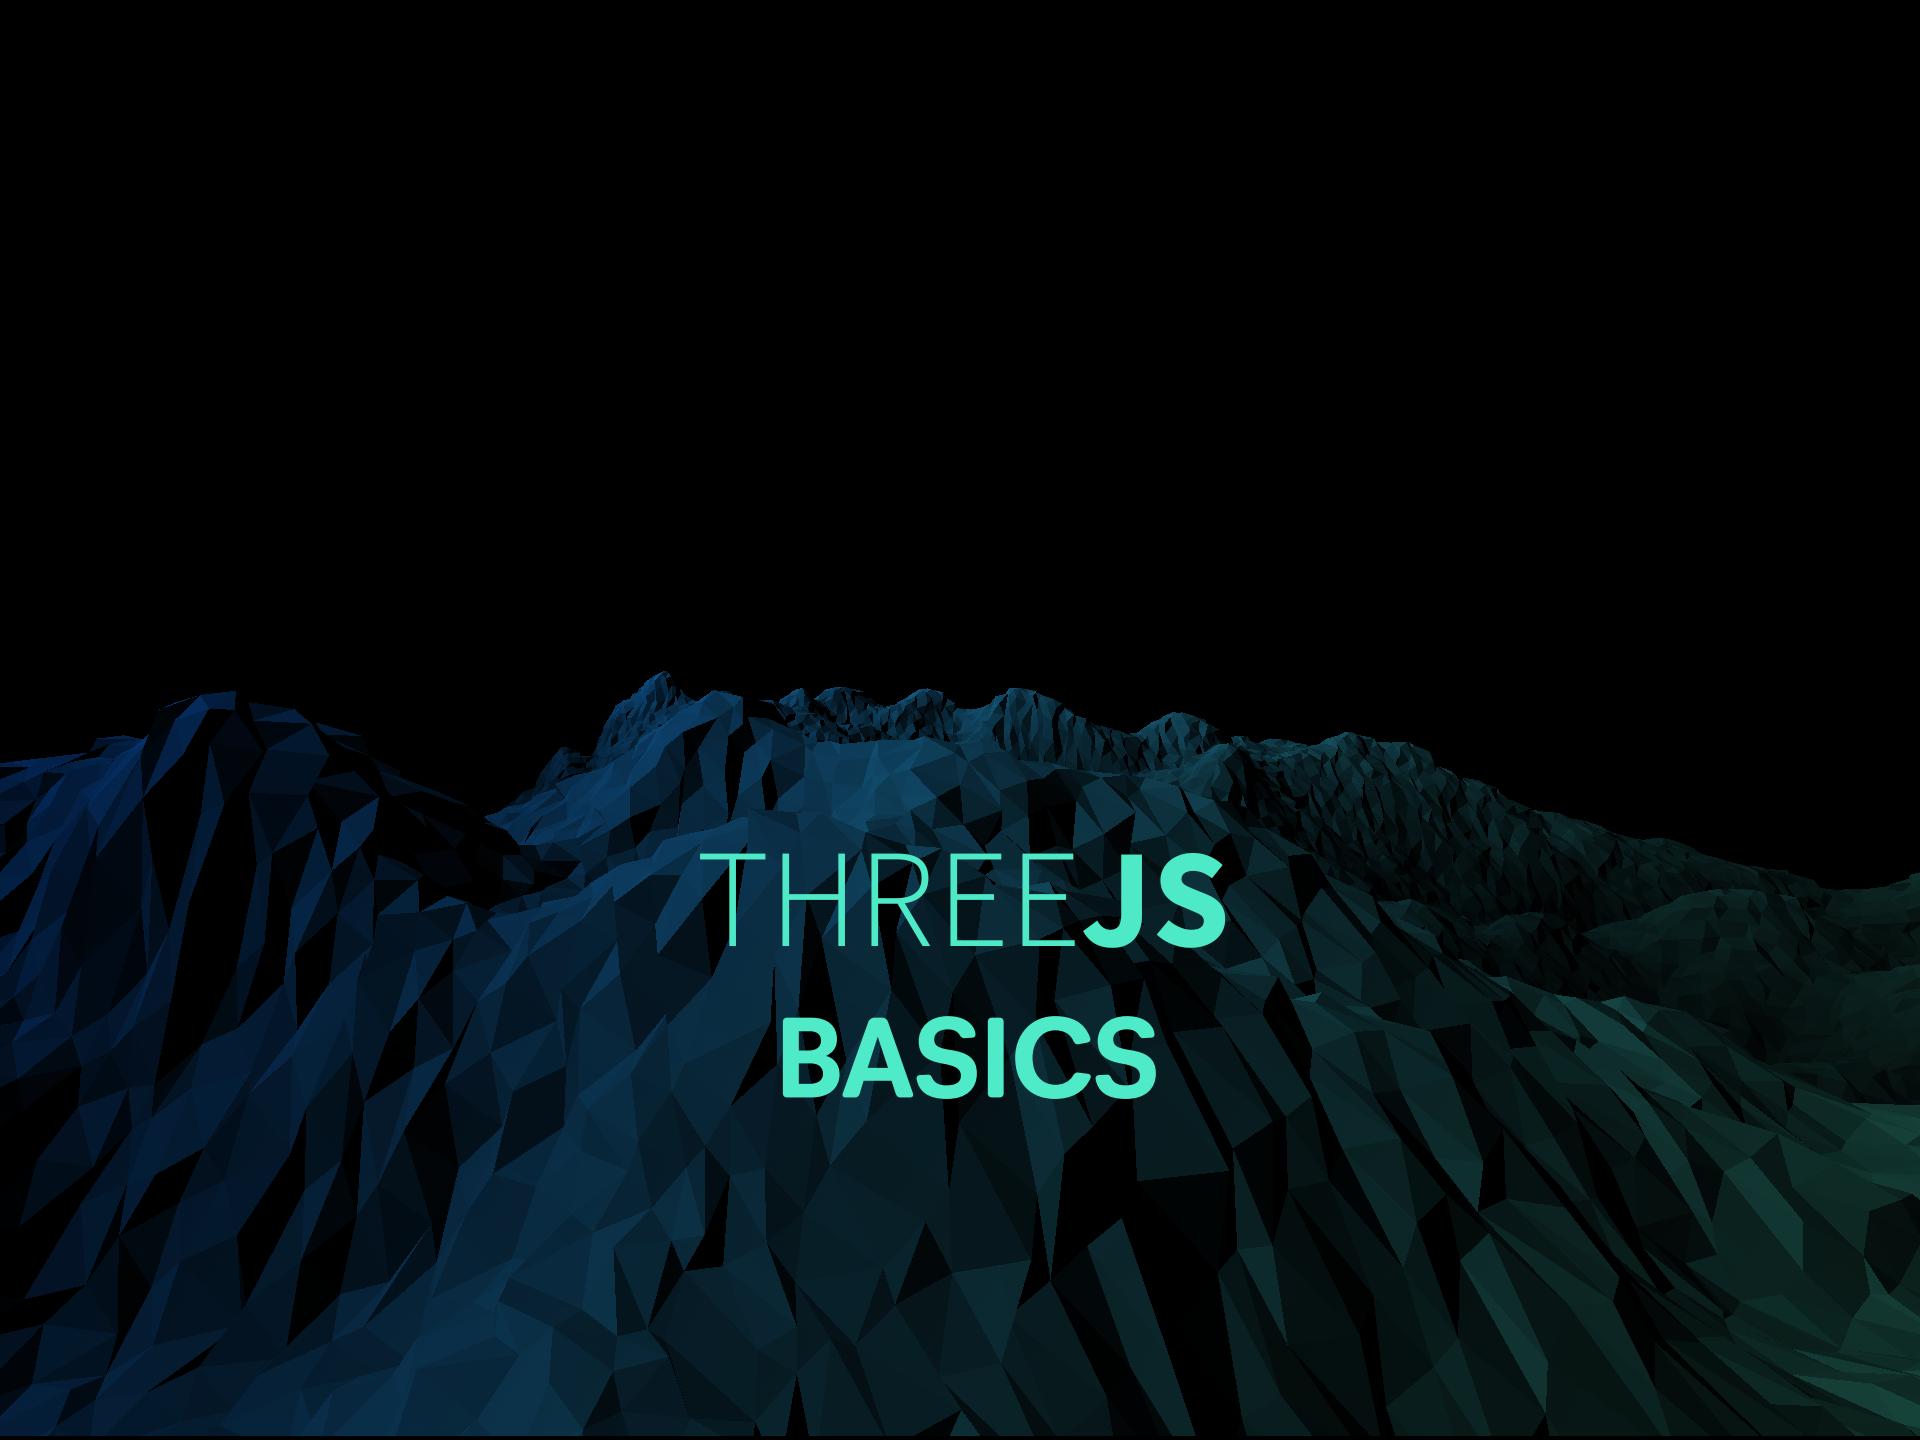

- Open the **Git** panel: `Ctrl+9`
- Open the **GitHub** panel: `Ctrl+8`

Or you can also toggle the Git panel from the Status Bar by clicking on the changed files icon:

To access the GitHub for this particular class, please follow the link below:

THREEJS BASICS

Rendering a Basic Scene

This is the first common pattern we are going to see in every Three.js app:

- Create a Renderer
- Create a Scene
- Create a Camera

The renderer is the place where we are going to put the result of our scene.

In Three.js we can have multiple scenes and each one can have different objects.

Renderer (WebGLRenderer)

scene1

scene2

```
renderer.render(scene1, camera);
```

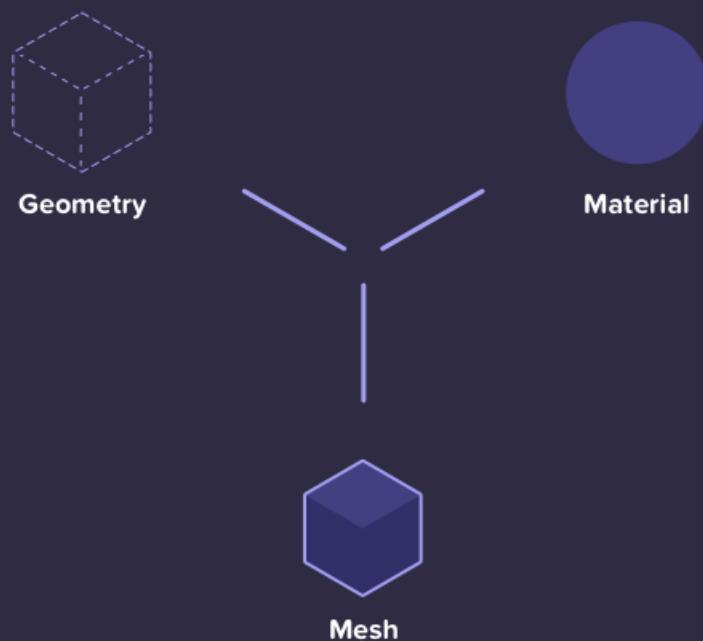

```
renderer.render(scene2, camera);
```

Rendering a Basic Scene

The second common pattern is adding objects to the scene:

- Create a Geometry
- Create a Material
- Create a Mesh.
- Add mesh to scene.

In Three.js a Mesh is the composition of a Geometry with a Material.

00_BasicStructure Example

Opening the example 00_BasicStructure, you will see the fundamental files needed for a project.

The files include the main **index.html** (show below), which has a standard HTML page formatting. To include the Three.js library, there are two ways: (1) either you load it locally – as in the example below, or (2) you use the CDN link (uncommented in this case).

In addition, the HTML code includes the **index.js** file, which is the file that will include our JavaScript code.

The screenshot shows a code editor interface with a sidebar on the left displaying the project structure:

- GitHub
- 00_BasicStructure
 - build (with three.min.js)
 - css (with style.css)
 - js (with index.js)
- index.html
- README.md

The main editor area is titled "index.html" and contains the following code:

```
1  <!DOCTYPE html>
2  <html lang="en" >
3      <head>
4          <meta charset="UTF-8" />
5          <title>Three.js</title>
6          <!-- Simple reset to delete the margins --&gt;
7          &lt;style&gt;
8              body { margin: 0; }
9              canvas { width: 100%; height: 100% }
10             &lt;/style&gt;
11             <!-- Three.js CDN --&gt;
12             &lt;!-- &lt;script src="https://cdnjs.cloudflare.com/ajax/libs/three.js/96/three.min.js"&gt;&lt;/script&gt;--&gt;
13             &lt;script src="build/three.min.js"&gt;&lt;/script&gt;
14         &lt;/head&gt;
15         &lt;body&gt;
16             <!-- Our code --&gt;
17             &lt;script src="js/index.js"&gt;&lt;/script&gt;
18         &lt;/body&gt;
19     &lt;/html&gt;</pre>
```

00_BasicStructure Example

Here we create an empty scene where we are going to add our objects (i.e. mesh), and also setup the camera, passing as parameters the FOV, the Aspect Ratio, near plane and far plane, and finally to add the WebGLRenderer, and pass to it the size of the window as a parameter and then append it to the DOM.

```
// Create an empty scene -----
var scene = new THREE.Scene();
// -----

// Create a basic perspective camera -----
camera = new THREE.PerspectiveCamera(35, window.innerWidth /
| window.innerHeight, 300, 10000 );
// -----

// Create a renderer with Antialiasing -----
var renderer = new THREE.WebGLRenderer({antialias:true});

// Configure renderer clear color
renderer.setClearColor("#000000");

// Configure renderer size
renderer.setSize( window.innerWidth, window.innerHeight );

// Append Renderer to DOM
document.body.appendChild( renderer.domElement );
// -----
```

00_BasicStructure Example

The next part demonstrates how we create an object (box in this case), create a material, and apply these two to the mesh object that is finally added to the scene. In addition, the function render takes care of the animation of the object, using the scene and camera settings.

```
// Create a Cube Mesh with basic material -----
var geometry = new THREE.BoxGeometry(100, 100, 100);
var material = new THREE.MeshBasicMaterial( { color: "#433F81" } );
var mesh = new THREE.Mesh( geometry, material );
mesh.position.z = -1000;
// ----

// Add mesh to scene
scene.add( mesh );

// Render Loop
var render = function () {
    requestAnimationFrame( render );

    mesh.rotation.x += 0.01; //Continuously rotate the mesh
    mesh.rotation.y += 0.01;

    // Render the scene
    renderer.render(scene, camera);
};

render(); //Run the function render
```

00_BasicStructure Example

To run this example, open the **index.html** in your Chrome browser.

Geometry, Material and Mesh

A Geometry is the mathematical formula of an object, providing for us the vertices of the object we want to add to the scene.

If you take time to look through the code for Three.js you'll see a lot of objects "inherit" from Object3D. This is a base object which contains some very useful properties, such as the **position**, **rotation** and **scale** information. In particular our Sphere is a Mesh which inherits from Object3D, to which it adds its own properties: **geometry** and **materials**.

SphereGeometry

BoxGeometry

ConeGeometry

CylinderGeometry

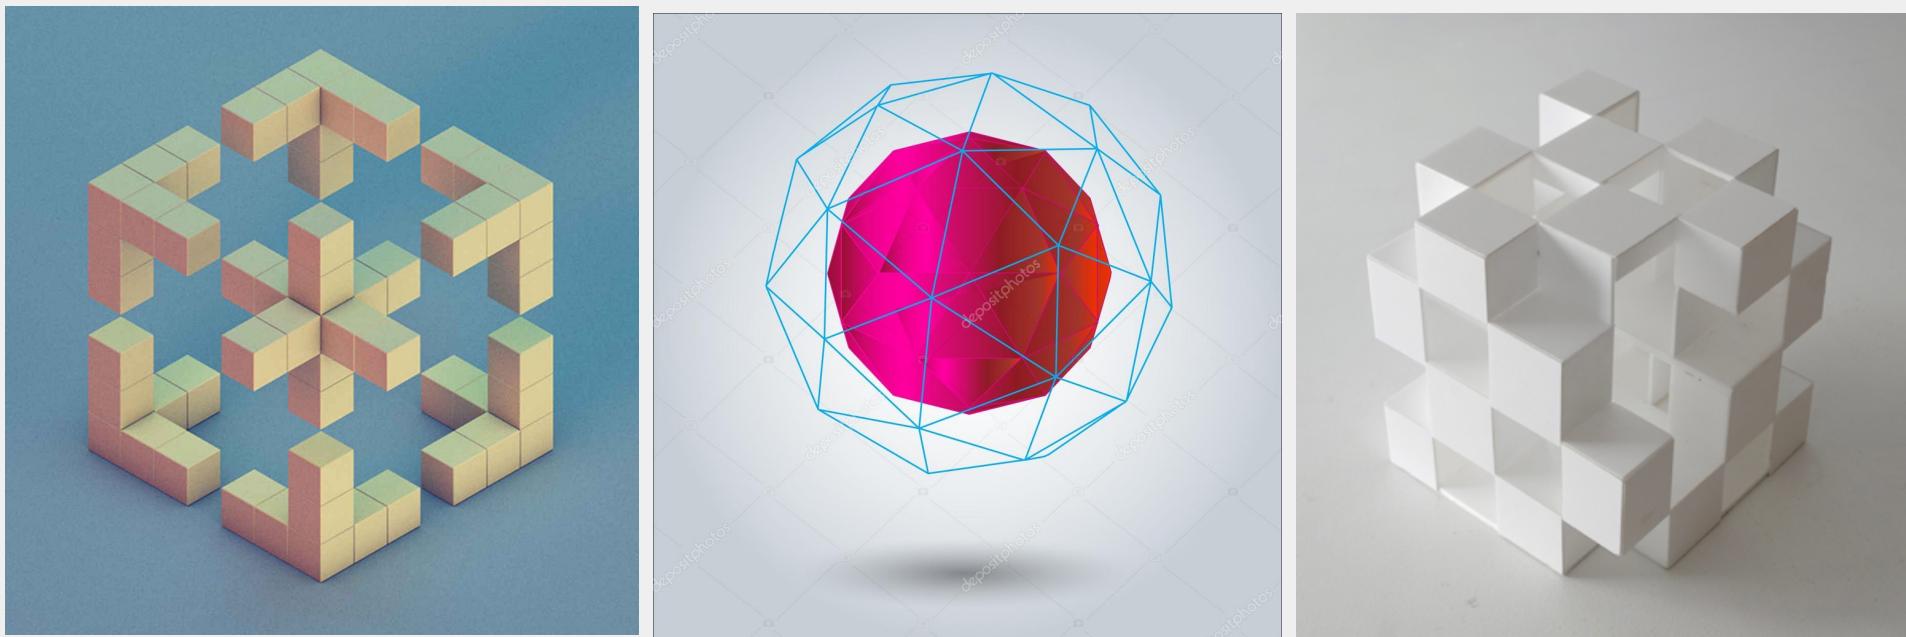

Exercise: 02_Exercise-GeometriesAndMaterials

In this exercise, you are asked to utilize the content discussed today and extending it to accommodate the following:

- Create a composition that consists of multiple geometric objects
- Each object (or groups of objects) have different material
- Each object (or groups of objects) have a different position, rotation, motion

This exercise is part of your work, and it is needed to be demonstrated (GitHub).

Evidence: creativity, aesthetic design skills, and experimentation.
